## Current Design limitations:

### Safety:

- Braking
- Seat angle
- Bamboo canopy
- Unprotected wheels
- Protruding wheel hubs
- Wooden or plastic pedals
- No lighting

### Comfort

- Forward facing seat
- No functional suspension
- Small customer area

### Gearing

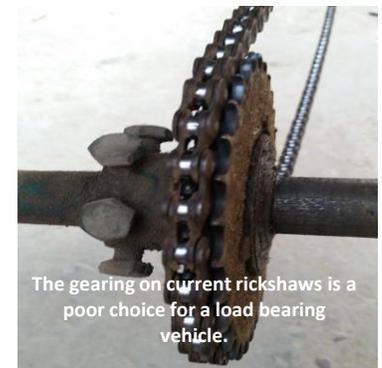

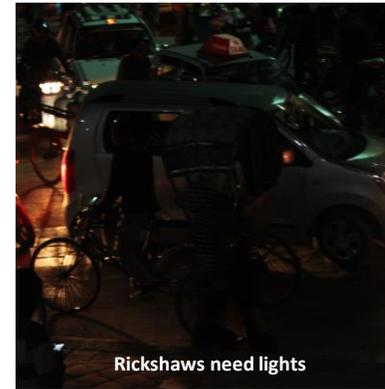

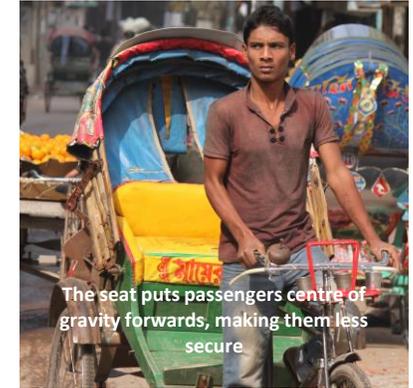

- Single speed

### Weight

- Often times greater than 70kg

### Aesthetics

- 'romantically' traditional

# Drive Train Concept Direction Recommendations

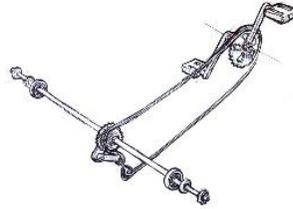

## Drive Train initial prototyping & testing.

### Concept Direction #1

By retaining the current simplicity and minimal parts of the single speed drive, this direction allows us to test the impact of improved componentry without added trade-offs that come with gearing. We can also easily test a manual shift second cog on the chainset, along with a simple chain tensioner to achieve the very simplest of gearing options.

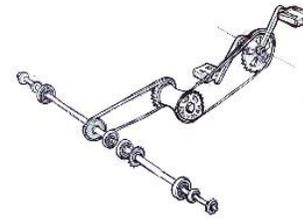

### Concept Direction #2

Including this direction in our testing allows us to offer an upgrade step not too far removed from the current set up, with significant performance improvement for a relatively small rise in cost.

If we can explore making each vehicle adaptable to a range of gearing options this could teach us how to instill upgradability into the final design.

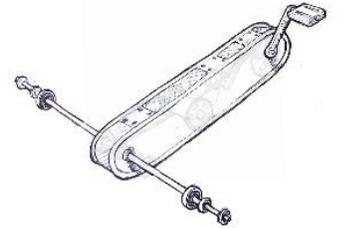

### Concept Direction #3

A Jackshaft with internal hub gives us the next gearing upgrade to test. This mid-mounted drive allows modern internal gearing technology to be plugged in to the vehicle while maintaining the backup of the single speed option.

Splitting the axle lets us test plug and play electric assist options that don't interfere with the manual drive.

### Concept Direction #6

A structural casing for the drive could reduce maintenance and wear and enforce a rigidity and maximum power transfer between the Driver and the road. It also offers a solid backbone to build a vehicle around. By testing this direction we can discover the trade offs and bonuses to having a neat modular drive mechanism that hides the messier mechanical elements away.

BELINKY JACK SHAFT

BICYCLE DESIGN TRIKE KIT

DELTA TRIKE SPLIT AXLE

**Drive Train Concept Direction #3**

A Jackshaft with internal 3-5 speed hub allows modern internal gearing technology to be plugged in and out of the vehicle while maintaining the backup of the single speed option. Splitting the axle creates an easy platform for incorporating electric assist options that that don't interfere with the mounting of the manual drive.

**PROS**

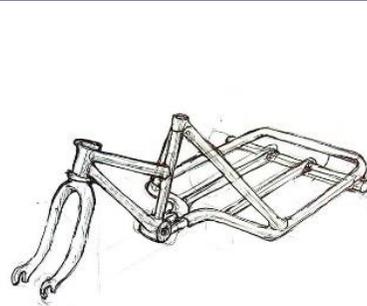

- No sensitive components hanging below chainline
- Upgradable/downgradable
- Simple electric assist plug in
- Improved range of operable terrain
- Plug and play/easily replaced during service time to keep vehicle on the road/operable.

**CONS**

- Harder to repair hub drive failures.
- Additional axle bearings required
- Increase in cost
- Requires a more rigid frame

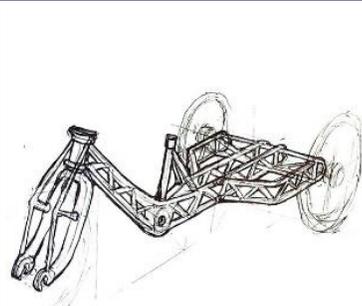

## 4 concept frame designs carried through initial prototyping & testing.

### Concept Direction #1

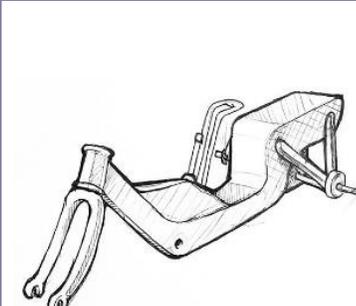

Prototyping this frame will allow us to compare a conservative approach to our other frame prototypes, while continuing to learn more about the current cycle rickshaws and their mechanics/garages. It also provides us with a gentle start to gleaming user response rather than offering up purely radical approaches.

### Concept Direction #3

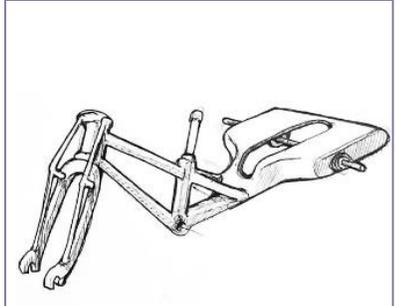

This frame may end up being an exercise in over-engineering, but it could also put Tata out of business. Like the monocoque frame trussed construction has proven itself in the motorbike and scooter industry. This direction also has the strongest sense of modularity.

### Concept Direction #5

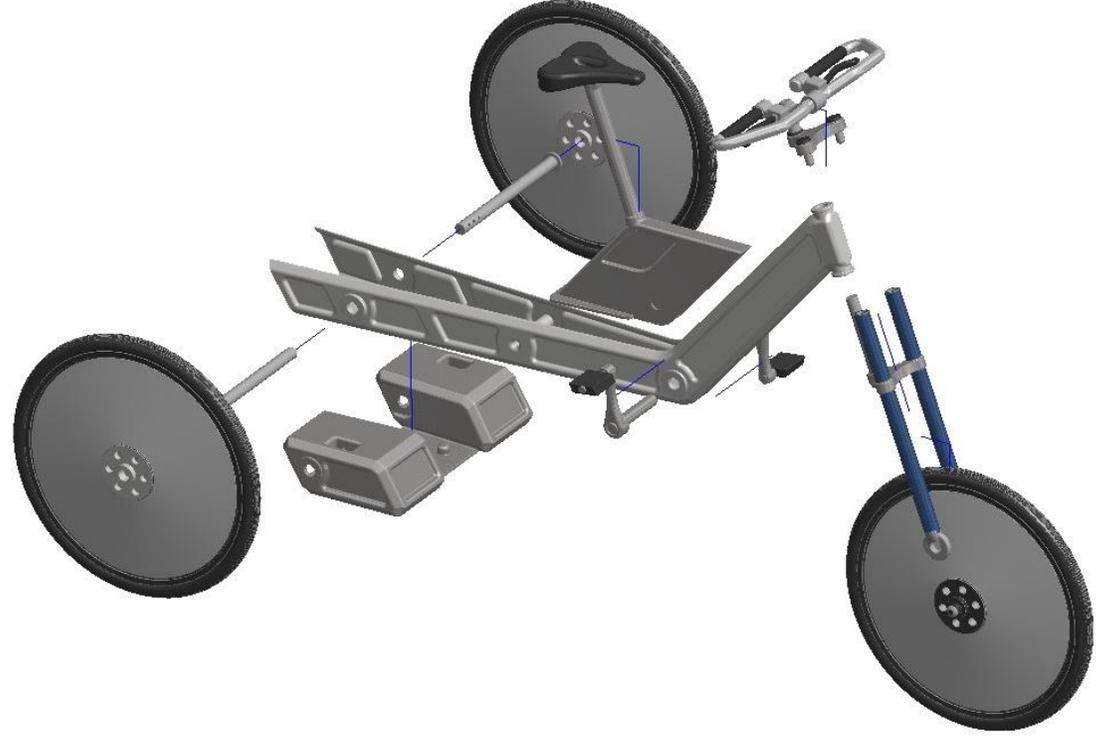

A monocoque frame could provide just the game changing aesthetic and speedy manufacturing that we need to succeed at scale. It defies the associations that tubular construction carries and gives us a different set of forms to explore alongside the other concept directions.

### Concept Direction #6

Aluminum is struggling to get past the sensibilities of steel in the teams mind but gauging stakeholder response and performance against the other frame prototypes will help us determine whether trade off of weight savings and corrosion resistance in exchange for reparability & price is justified.

# G7. Backend Management

Backend management systems requires computation resources, e.g. CPU, Memory, I/O and etc... Therefore in order to achieve a better performance and scalability at a lower cost but yet still remain ease of management, the backend management architecture for the pedicab fleet management system should be divided into two different layers, an application server and a database server. Separating the database management system (DBMS) from the rest of the environment help to eliminate the resource contention between the application and the database.

The diagram below shows the overall connectivity of the pedicab system. The user refers to web user and the user who is waiting for the pedicab on the street. Both kind of users can check the status and the availability of the pedicab by accessing into the application server. When a pickup request is made, the application server will check with the database server and assign the closest pedicab available to answer this request.

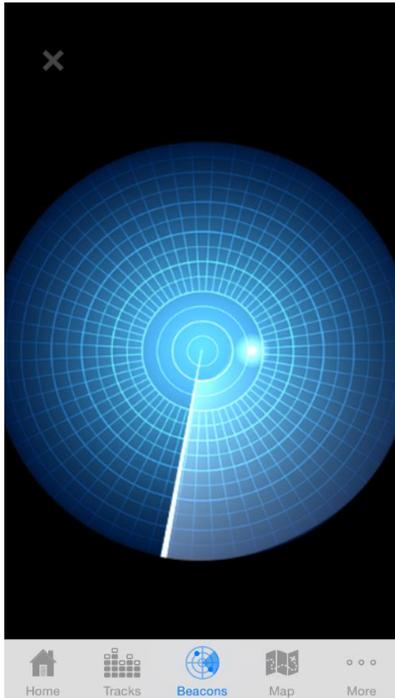

## Smartphone Apps

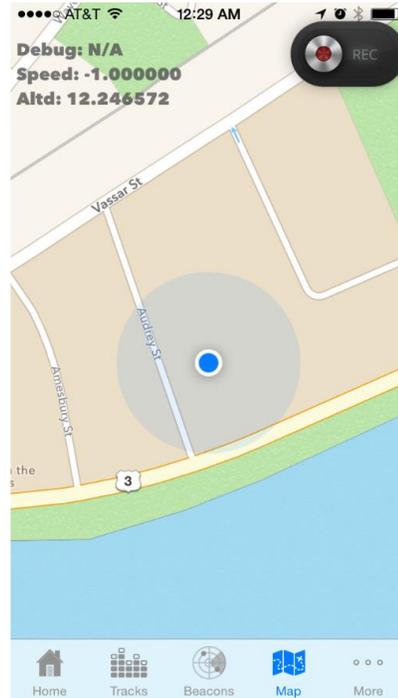

The Pedicab Smartphone app could provide the following core functions:

1. Pickup request.
2. Scanning of the nearby Pedicab.
3. Real time map
4. Real-time route Tracking
5. Payment
6. Driver evaluations
7. Trip tours
